Note to Readers

Changes in the descriptors of five of the six tourism regions used in the study **Impacts of Coastal Energy Development on New Jersey's Shorefront Recreational Resources** occurred after final editing of this appendix volume and are not included in it.

Consequently, the reader is asked to substitute the descriptors found in this volume (listed below, left) for those found in the summary report (listed below, right).

Former Version	Final Version
Densely Settled Commuter Suburb	Non-Seasonal Suburban
Northern Shorefront Year-Round and Rural Community	North Shore Non-Seasonal/Rural
Northern Shorefront Seasonal Communities	North Shore Seasonal
Southern Shore Year-Round and Rural Community	South Shore Non-Seasonal/Rural
Southern Shorefront Seasonal Communities	South Shore Seasonal

The tourism region **Resort Gambling** remains unchanged.

APPENDIX J. CASE STUDY APPLICATIONS OF THE COASTAL TOURISM RESPONSE MODEL

Introduction

This section of the report presents the analyses of five case studies by the Coastal Tourism Response Model (CTRM). The case studies are hypothetical situations in which prototype facilities are proposed for selected municipalities. The purpose of the case studies is to (1) test and demonstrate the various analyses carried out by the CTRM; (2) indicate the range of impacts that can result when the same facilities are located on different sites or different facilities are located on the same site; and (3) test the underlying principle of the model: that tourist response is not only a necessary variable for an accurate computerized analysis of energy facility impacts, it is also a factor of paramount importance to planners and policy analysts who direct the course of energy development on the New Jersey shorefront.

The five case studies presented here are a subset of the 1,305 possible combinations of the 15 prototype energy facilities in the 87 coastal municipalities that are included in this study. Figure 1 is a map showing the study area municipalities. The model's additional capability for handling major facility malfunctions, actual facility descriptions, and unique environmental conditions enable it to address a great range of social and economic impacts. Selection of the five cases was based on the feasibility of placing these facilities in particular municipalities. However, these case studies should in no way be construed as an assessment or review of actual development plans for the sites. The following scenarios were selected for the case study application:

Case Study #1	Lacey Township, Ocean County Coal-fired power plant	Map number Facility number	43 10
Case Study #2	Lacey Township, Ocean County Support base	Map number Facility number	43 1
Case Study #3	Manasquan Township, Monmouth County Support base	Map number Facility number	26 1
Case Study #4	Middle Township, Cape May County Coal-fired power plant	Map number Facility number	78 10
Case Study #5	Ocean City, Cape May County Support base	Map number Facility number	72 1

Case Study Comparison

Table 1, Comparison of Case Study Indicators summarizes some of the essential statistics produced by each of the five case studies. Also included are visitor expenditure and enumeration data for the selected municipalities. To simplify the analysis across the 11 years evaluated, figures are taken from the year of peak construction expenditures and the second year of facility operation.

Table 1 indicates that the social and economic impacts of facility construction and operation vary considerably depending on the facility's scale and the level of tourist activity in the area. Given certain combinations of variables, employment losses may be substantial in New Jersey and even greater in the shorefront study area. Severe repercussions on employment and sales in the local tourism industry could result from the environmental impact on recreational resources associated with energy facility development. The percentage and scale of receipts and value-added lost in some economic sectors will result in hardship for many individuals. Although the net employment impact may be positive, many jobs in local tourism industry establishments will be eliminated. Some of these unemployed persons will be employed in nearby municipalities that absorb some of the diverted tourism trade, but few of them will be suited for employment in the manual construction and plant operation jobs which are created.

The case studies demonstrate that some facility-related impacts are not of major concern for the New Jersey shorefront. The densely-settled shorefront with its abundant supply of second and seasonal homes can accommodate the housing needs of those working at the facility with little adverse effect. Because of the proximity of two large urban centers, New York and Philadelphia, and the generally high population density of New Jersey, relatively few families will migrate to the plant location. In general, the impact on municipal finances and housing demand can be expected to be minimal.

The study determined several factors that contribute to the loss of tourism but which do not cause dramatic differences among the case studies. Expenditures per person-day vary according to visitor accommodation, but differences in expenditures and the proportion of visitors in certain accommodations is relatively small and do not result in significant differences. Similarly, the facilities differ in the nature of the environ-

mental impacts that can be expected to occur. Visitor response to change in recreational resources often varies by as much as a factor of two between types of resources and from tourism region to region. However, this form of variation is small relative to the difference in the number of visitor person-days from municipality to municipality. A notable exception to this conclusion is the response of visitors to an environmental event such as an oil spill. Depending on the season of the occurrence, an oil spill in an area of moderate to high tourist activity could result in severe social and economic impacts.

A key indicator in table 1 is the number of tourists diverted from the environmentally affected municipality. The loss of expenditures that would have been made by these tourists (i.e., tourism industry final demand loss) can adversely affect the local economy. By looking at the number of travelers lost as a fraction of total tourism normally visiting the municipality, and the change in final demand as a fraction of the total tourism expenditure, the severity of the impact can be gauged. For example, during the peak construction year of a support base in Lacey Township (Case Study #2) over 171,000 visitor-days or almost 24 percent of the total tourism in the municipality will be diverted to another location. The absence of expenditures by these ourists will result in a loss of approximately $5.6 million in tourism industry final demand. Over $2.8 million of this loss is borne by establishments closely related to the tourism industry in which travelers make their expenditures for lodging, eating, drinking, and amusement. This expenditure is a considerable proportion (32 percent) of the $8.9 million in recepits reported by firms within the municipality in primary tourism industry economic sectors, which include lodging, eating, drinking, and amusement. This proportion somewhat overstates the scale of impact both because visitor expenditures for these items correspond to receipts in a range of economic sectors broader than the totaled sectors and because travelers lodged in Lacey Township spend money in other nearby municipalities offering other recreational services. Of course, this local impact is greater than impacts at the regional and state level because many of the travelers diverted from the municipality are received by other shorefront municipalities reducing the net loss for all municipalities.

Of the five cases shown, the impact on the local tourist economy is greatest in Case Study #5, a support base in Ocean City. While the percentage of tourists diverted from the municipality may be relatively small compared to the other case studies, the

magnitude of Ocean City's tourism economy (totaling 5.2 million visitor-days, or 6.8 percent of total visitor-days at the shorefront) results in substantial impacts to Ocean City. The number of tourists lost will be 1.3 million visitor-days in the peak construction year and 1.3 million during a typical operation year. The effect on local economic activity will be $44.4 million lost during peak construction and $41.5 million lost annually during the operating phase. This case study, as well as each of the other studies, indicates a correlation between large losses in actual dollars and those areas along the shorefront where seasonal tourism is most active.

Of the five case studies, the greatest percentage of loss to the tourism industry would occur in Case Study #4, coal-fired power plant in Middle Township. During construction, the municipality would lose over half of its tourism industry receipts. Most severely affected would be restaurants, motels, and similar tourism-dependent establishments. Middle Township incurs relatively heavier losses because it contains a higher percentage of visitors in hotels and motels than the other case study municipalities. The dollar loss for the local economy associated with a visitor-day of a traveler lodged in a hotel or motel is almost twice that of a visitor-day of a seasonal home occupant ($54 - $28 in 1982). The actual loss to persons both inside and outside New Jersey is much closer because the value of the seasonal home rental would be included in such a calculation (seasonal home visitor's total loss per visitor-day rising to $41).

Another useful indicator of a facility's impact is the loss or gain in the employment of residents in the state. For coal-fired power plants 1,361 person-years of employment are directly created by the construction of the plant during the peak year and 102 person-years are generated during each year of operation. For the support base, 47 person-years are required for construction and 100 person-years are created for annual operation. The net employment effect of a facility takes into account the direct, indirect, and induced employment generated by facility construction and operation, combined with the overall job losses due to the loss of tourism in the state. As shown in table 1, the two coal-fired power plants result in a fairly close gain in employment during the construction year (2,720 person-years in Case Study #1 and 2,466 in Case Study #4). During the operation year, however, the impacts are considerably different. In Lacey Township, the operation of the plant would result in a net addition of 157 person-years of employment. In Middle Township, the operation of the same plant results in a net loss of 68 person-years of employment annually. It is worthy to note that

of the two townships, Middle's tourist activity represents 2.6 percent of total shorefront tourism, while Lacey's tourist activity accounts for only .95 percent. Furthermore, local tourism amounts to about 2.0 million visitor-days in Middle compared to 730,000 in Lacey.

Alternative use of model programs to produce separate analyses of the impact of first the facility and second the response of travelers to change in environmental resource sheds light on the origin of impact. These impacts are provided in table T20 of each case study. Due to its greater scale, the coal-fired facility results in more employment, generating 2,720 person-years of employment in year three due to direct purchases and employment. This particular impact will not vary when the facility is analyzed in other sites because location will have little impact on either the make-up of suppliers or the number of out-of-state employees hired. However, loss of employment in a municipality will follow from negative tourist responses. For example, the operation of a support base in Ocean City would cause a net loss of 431 person-years of employment, 7 times the loss associated with the same support base located in Lacey Township. In each of the case studies, the employment loss associated with tourist response is essentially offset by the gains made from the construction and operation activities of the facility. Because the losses and gains in employment occur in different sectors of the economy, unemployment as a result of a facility's presence will be experienced by some, despite an overall gain in employment. Certainly, much of this unemployment will be felt by those employed in largely local tourism-related sectors depressed by negative tourist responses to the presence of the facility. Case Study #5 is the most affected in this way, largely because this is the location where the most tourists are found, tourists who are more responsive to a loss in recreational resources. As evidenced in differences between Case Study #1 and Case Study #2, the extent of environmental change also is a secondary influence.

Another important indicator selected for display in table 1 is the measure of value added. Value added is generally considered to be a more accurate measure of the change in the state's economic activity than is the gross economic output measure provided in I/O table T20. This is because by definition the gross output measure includes all the direct, indirect, and induced outputs, resulting in the double counting (or, in fact, multiple counting) of the value of the goods and services that are purchased from businesses in the state at each stage of the chain of direct or induced effects. Value

added, on the other hand, represents the gross economic output minus the goods and services (other than labor) purchased to produce the output. That is to say, it measures the value actually added to the product at each stage of production. Thus, value added consists mainly of wages and salaries, proprietor's incomes, corporate profits, and taxes.

Table 1 indicates that value added results differ according to the location of the facility. During the peak construction year of a coal-fired plant, the value added figures for the Lacey Township and Middle Township cases are fairly close at $76 million and $72 million, respectively. During the operation phase, however, Lacey Township experiences an increase of almost $11 million in value added, while the increase in Middle Township is only $6.6 million. These operation year differences are once more attributable to the difference in tourist activity in each municipality.

Each of the three case studies considering a support base, Case Studies #2, #3, and #5, places the base in a different county. Case Studies #2 and #3, Lacey Township in Ocean County and Manasquan Township in Monmouth County, contribute $6.8 million and $6.9 million, respectively, in value added to the state's economy during the construction year. During the operation year, value added amounts to $6.5 million and $6.6 million. Though Lacey accounts for more of the total shorefront tourism than does Manasquan, both receive less than one percent of the total. In contrast, the support base in Ocean City, which accounts for 6.8 percent of total shorefront tourism, generates an overall decrease in value added in the state. There is a $600,000 decrease during the construction year and a $270,000 loss during annual operation.

In addition to the five case studies, a model analysis was performed on a hypothetical oil spill creating a notable impact for two months, June and July, on the beach of Ocean City, Cape May County. These months experience 42 percent of all visitor activity. This analysis considers only the loss of economic activity associated with visitor response. The results indicate that an oil spill would cause serious loss whose impact would last over time unless otherwise addressed by actions such as advertisement or lower rental rates. The analyses also points to the importance of the time of year when the oil spill occurs.

The analysis of the oil spill event showed an immediate diversion of 800,000 visitor-days from the area; two years later, 34 percent of the visitors diverted would still

not be replaced. For the entire shorefront, the tourism industry final demand loss would equal $5.7 million during the year of the spill event. However, this represents only 20 percent of the severe loss which would be experienced locally. For New Jersey, the oil spill would result in the loss of 230 person-years of employment and $4.1 million of value added in the year of the event. Further, the two-month event would result in a continuing impact which would decline slowly, with a loss of 68 person-years of employment for two years following the oil spill.

CASE STUDY # 1
COAL-FIRED POWER PLANT IN LACEY TOWNSHIP

CASE STUDY #1
COAL-FIRED POWER PLANT IN LACEY TOWNSHIP

The Context: Lacey Township

The first case study assesses the social and economic impacts of a coal-fired power plant in Lacey Township. Lacey Township is located in Ocean County and is discussed in more detail in Appendix E, is the largest coastal county in the study area. Ocean County's population doubled in the 1960's and increased by 66 percent in the 1970's, making it the fastest growing county in the state. Even more dramatic is Lacey Township population increase in the last decade of almost 300 percent. Land use in the Township is primarily residential and rural, with industrial and commercial real property comprising only 10.3 percent of total assessed valuation. The Garden State Parkway passes through the township, providing excellent north-south access.

Lacey Township is classified as a north shore non-seasonal/rural community. The characteristics of municipalities in this classification are listed in Appendix E. Lacey Township's population density is .3 persons per acre. Only 19 percent of the housing is for primarily seasonal use. The measure of intensity of residential development reflects both the quality and density of dwelling units; it is derived from the assessed value of the homes and the ratio of the assessment to true market value. In Lacey Township this intensity is $6,675 per acre. The market value of a typical home in the township is $47,700. One of the township's major recreational attractions is the abundance of marina ships (approximately 1,000 of them) located along the western shore of Barnegat Bay.

Energy Facility: Coal-fired Power Plant

The energy facility used in this case study is a 500 megawatt coal-fired power plant with a total capital cost of $468.8 million to be constructed over a five year period. The facility would include a closed cooling system, minimizing the need for water from adjacent Barnegat Bay.

As shown in the facility environmental impact assessment matrix at the end of this appendix, activities during site preparation, construction, and operation of the plant can

affect numerous changes in the environment both because of ecologically and qualitatively. For example, faunal abundance may decrease the removal of surficial soils and vegetation during the site preparation phase. This activity may also generate a significant amount of dust that may detract from the appeal of Lacey Township to tourists.

The environmental changes are summarized and evaluated in the Schedule of Environmental Changes (I/O Table T8) located at the end of this appendix. Perceivable thresholds for the change categories are provided in section 2.4 of the User's Guide. As shown in the schedule, the likelihood of a category one change (loss of access to a recreational resource) is high due to the preemption of a significant amount of waterfront acreage. A loss in the quality or degree of recreational opportunity is expected to occur during the third, fourth, and fifth years of the construction period as a result of the decrease in faunal abundance and traffic congestion caused by construction activity during these years. (Note that water depth and shoreline changes in this category are considerd to be low or minimal because in most locations in the study area a coal-fired power plant would receive coal by rail, minimizing the dredging and channeling activities that could cause these changes.) Beginning in the third year of construciton there is a high probability of the lowering of visual and other aesthetic qualities. While the major structures of a coal-fired power plant are quite high and visible over a large area, the plant's inland location would limit its visibility to less than one mile of coean front. The corresponding probability of visual marring of the ocean front is listed in the schedule as low. Finally, it is assumed that tourists do not perceive the operation of a state-of-the-art coal-fired power plant as producing toxic substances, pathogens, or hazardous substances. Consequently, the probabilities of the introduciton of hazards and temporary loss of resources due to pollution are minimal.

Impact Path 1: Purchase of Construciton Materials and Equipment

I/O Table T3, Schedule of Project Requirements

The first Imput/Output table, T3, shows the total capital cost of $468.8 million divided by the fraction of construction completed for each year of the construction period. The number of manual and non-manual construction employees is listed for each year of the construciton period, as seen in Appendix B. For the remainder of the 11-year

analysis period, the annual operations labor force in the manual and non-manual categories appears as 90 and 12 person-years, respectively.

Impact Path 2: Construction and Operation Employment

I/O Table T4, Directly Employed Migrants

Input/Output Table T4 shows, by municipality and year, the number of directly employed migrants drawn to the region by employment opportunities at the plant over the 11-year planning period. The 29 municipalities presented in the table are those within the 30-minute commuting zone around Lacey Township. As can be seen, eight municipalities are receiving migrant employees, totaling 24 person-years, of employment over the five-year construction period. In the peak of construction, year three, 97 migrants will be broufht to the region. Case studies of existing facilities show the smaller labor force neded for the operations phase is typically locally supplied. Consequently, beginning with the sixth year of the analysis period (the first year of operation) the table shows no migrant labor will be contracted to the region by the facility. The remaining 10 percent is provided by immigrants. However, when this percentage amounts to less than .5 of one person-year it is rounded down and a zero appears.

I/O Table T5, Directly Employed Previous Residents

During peak construction of the plan, 73 percent of its manual laborers and 46 percent of its non-manual laborers are expected to be drawn from the working-age population of 117,318 currently residing within the commuting zone of Lacey Township. A presentation of these workers by municipality and year appears in I/O Table T5. During the construction period (the first five years of the analysis period) a fairly normal distribution exists, increasing substantially in the second year, peaking in the third, and tapering off during the fourth and fifth years. In the sixth through eleventh years, the relatively smaller operations labor force is constant. Dover, Brick, Lakewood, and Howell Townships lead the 44 municipalities with the largest numbers of previous residents employed. During the peak construction year, the third in the 5 year construction period, 171 Dover Township and 145 Brick Township person years of employment will be needed at the plant. During the construciton period 372 person-

years from Dover Township and 315 person-years from Brick Township will be required. During the six years of plant operation person-years of employment presented in table T5 17 will be supplied by Dover Township and 15 will come from Brick Township.

I/O Tables T6-A and T6-B, Unsupplied Family and Single Person Housing Demand

Input/Output Tables T6-A and T6-B present the unsupplied family and unsupplied single-person housing demand in each municipality within a 30-minute commuting zone around the facility. As discussed elsewhere, the abundance of second and seasonal homes on the New Jersey shorefront is sufficient to meet new housing demand of migrant employees in the foreseeable future. Consequently, many I/O tables T6-A and T6-B will show no housing demands of this type. In Case Study 1, family housing demand in municipalities with populations exceeding 15,000 with the commuting zone is 63 units in the peak construction year. Because this represents 0.08 percent of the total number of owner occupied housing, an excess housing demand cannot be said to exist, particularly given the effects on housing demands from normal housing unit turnover rates and the number of seasonally rented homes.

I/O Table T7, Facility Employee Income

Input/Output Table T7 presents the earnings of both resident and migrant employees for each year of the 11-year analysis period. For the 5-year construction period, the patern of increases and decreases in facility employee income from year to year corresponds directly to the change in the number of employees shown in I/O Tables T4 and T5. Consequently, the municipalities that are the recipients of the greatest amount of employee income are Dover and Brick Townships. In Dover Township, facility employee income peaks at $6.4 million in the third year and totals $13.9 million over the five-year construction period. In the operation phase, $497,000 of income is earned annually by Dover residents. To determine the increase earned by either the migrant or resident employee groups, divide the number found in the appropriate table (Table T4 for Directly Employed Migrants Brought to the Region and Table T5 for Directly Employed Previous Residents) for the municipality and year desired by the combined total of the two tables for the desired municipality and year desired. For example, to determine the facility employee income for migrant workers from Brick Township in the fourth year of construction, divide the number of Brick's migrants (8) for that year (found in Table T4)

by the total number of employees (71) (found by adding 8, the migrant contribution from Brick to 63, the number of Brick's directly employed previous residents in the fourth year of construction, found in Table T5). The result of this calculation is .11, which is multiplied by $2.353 million (the total facility income for Brick employees in the fourth year of construciton, found on Table T7). To determine the portion of total facility income earned by migrant employees from Brick Township in the fourth year of construction, or $265,126.62.

Impact Path 3: Tourist Response to Environmental Impacts

I/O Table T9, Tourism Diverted from Each Municipality

Input/Output Table T9 shows the number of tourists, in person days, diverted from the environmentally affected municipality which, in this case, is indicated as #43 Lacey Township. The 11 columns represent each year of the analysis period; the 20 rows corresponding to the 20 visitor types. These 20 types are keyed to the list of visitor group types found at the end of this appendix. Each visitor group type is denoted by a type of accommodation and activity. For example, the fifth row refers to the fifth visitor type, campground/shorefront recreation, which (in this case) will be diverted to other shorefront municipalities at the rate of 1,693 person-days in the first year, peaking at 10,141 person-days in the fifth year. Between 8,000 and 9,500 person-days of tourism will be lost during each successive year of operation. Category one of the 20 visitor types, seasonal home/shorefront recreation, incurs the greatest losses of the 20 categories, amounting to almost 59,000 person-days in year 4. Ninth through twelfth categories indicates no diversion of tourists because campsites do not exist in Lacey Township, so that no visitors are present in this accommodation group. It is useful to compare the total losses across all categories for a single year, (e.g., the peak year of construction) with the total number of visitors normally expected in the municipality. Information on total visitors can be found in the Inventory of Visitors in Chapters 2 and 3.3 of the text. In Case Study #1, the number diverted in year 3 is 239,464 visitor-days, 32.92 percent of the total annual visitor-days of 727,341.

I/O Table T10, Tourism Lost from Shorefront Study Area by Each Municipality

Input/Output Table T10 is similar to the previous table, yet differs by representing the tourism lost by the facility location from the entire shorefront region. The relative ranking of the 20 visitor groups is the same as if appeared in Table T9, although in the present table but these losses are considerably smaller. During the construction phase, less than 25 percent of the total person-days diverted in the campground/shorefront recreation category are lost from the shorefront region entirely. For example, in the fifth year of this analysis, 2,282 person-days are lost from the shorefront region entirely, as compared to 10,141 person-days that are diverted to other shorefront municipalities. Tourism loss from the shorefront is less than tourism diverted from the municipality because many visitors who respond to environmental change will merely move their recreational activities to a similarly equipped municipality nearby. Again, the first category losses are the greatest of the 20 categories. The number of (seasonal home/shorefront recreation) person-days lost from the region during the peak construction year (year 3) is 56,286 visitor-days, or 8 percent of the total annual visitor-days in the municipality.

I/O Table T11, Tourism Lost from Shorefront Study Area from All Municipalities

Because Case Study #1 encompasses a single municipality, Lacey Township, Table T11 is identical to Table T10. For analyses of facilities affecting more than one municipality, Table T11 totals the number of person-days lost from the shorefront study area by each municipality for each of the 20 visitor types across the 11 year period of the analysis.

Municipal Areas Analysis: Municipal Social and Economic Impacts

I/O Table T12, Fiscal Impact From Migration

Input/Output Table T12 presents the net result of the increased revenue provided to municipalities by migrants to the area and the costs to the municipalities of providing services to those additional people. Non-zero figures appear only in those rows corresponding to municipalities listed in I/O Table T4 as being recipients of migrants, and then only to the construciton phase, because no operations phase migrants are

expected in this case study. The table shows that he cost of providing municipal services outweighs increased revenues. In Dover Township the net cost peaks in the third year at $290,000 and then becomes negligible by the end of the construction period. Other municipalities that would show small, temporary net fiscal losses during construction include Howell, Brick and Wall Townships and the city of Lakewood.

I/O Table T13, Value Lost by Seasonal Home Owners

I/O Table T13 estimates the opportunity cost to seasonal home owners in Lacey Township who forego personal or rental use of their homes. In this instance, the greatest losses are experienced in the third year at $1.6 million. Subsequent years show losses of approximately $1.5 million each. In a township of 1,241 seasonal homes, third year losses average $1,324 per household.

I/O Table T14, Tourism Industry Final Demand Loss

I/O Table T14 shows the loss in final demand incurred by the industries and establishments in Lacey Township dependent on tourist trade over each year of the 11-year analysis period. Each of the eleven rows in the table corresponds to a different category of expenditure as listed at the end of this appendix. In the table, the greatest losses can be seen to occur in the fifth category, eating and drinking establishments, where beginning in the third year, losses construciton period amount to over $6 million. No amount appears in the last category, gambling, which is not applicable to Lacey Township.

Regional Area Analysis: Shorefront Social and Economic Impacts

I/O Table T15, Regional Expenditures for Material and Equipment

I/O Table T15 expresses in thousands of dollars the expenditure within the shorefront counties on required material and equipment, by economic sector, for each year of the construction phase. A coal-fired power plant is in the first of six groups of direct purchase profiles. The coal-fired plant and other facilities in the group require substantial quantities of general industrial machinery and equipment. The associated inputs have been determined to come from twenty five specific economic sectors in

fixed proportions for all of the facilities listed in the group. In I/O Table T15, the first column identifies the economic sector receiving expenditures. These numbers are keyed to the list of Water Resource Council Sectors at the end of this appendix. For example, the largest amount of expenditures within the region for a coal-fired power plant are made in sector #47, primary metal industries, in which $7.3 million is spent in the third year of construciton along. This represents 50 percent of the total $14.6 million spent on regional expenditures for mateials and equipment in year three, which in turn represents 6.8 percent of the total capital expenditure for that year for facility construction (see I/O Table T3). The regional expenditure for materials and equipment amount is small because it does not include wages, profits, or material and equipment purchases made outside of the shorefront region.

I/O Table T16, Tourism Industry Final Demand Loss

Tourism person-days lost by each municipality from the shroefront (i/O Table T10) has been converted to tourism industry final demand loss in dollars and presented in I/O Table T16. This loss is distributed across all of the affected water resource council economic sectors. In this case only five sectors are affected. Sector numbers appear in the first column with losses traced across the 11 years of this analysis. Sector #56, services, experiences the greatest loss, a total of $6.5 million over the analysis period. Sector #54, wholesale and retail trade losses $4.9 million over the same period. Total tourism industry final demand loss in the region was almost $1.7 million in year three, or 87 percent of all tourist trade lost (see third column in I/O Table T19) because most tourist expenditures are made for imported goods.

I/O Table T17, Final Demand Change for Shorefront Study Area

Facility employee income is also distributed across the Water Resource Council sectors. Input/Output Table T7 presents the same information in a more detailed form, consequently a separate table for facility employee income is not provided. The positive regional economic changes of Impact Paths 1 and 2 offset by the negative regional economic change of Impact Path 3 are presented in I/O Table T17. The economic sector numbers do not appear here. The 11 columns represent each year of the analysis period, the 56 rows correspond to each of the Water Resource Council economic sectors. Instances of no or negligible impact are represented by a zero. None of the sectors are

shown to experience a negative net effect at any point during the 11-year period. Positive effects are of varying magnitude, as in sector #55, finance, insurance, and real estate, for instance, where the final demand change reaches $6.5 million in the third year of construction and maintains a $486,000 demand change for each year of operation; in sector #12, agriculture and fishery serices, the effect is minimal and limited to the construction period.

I/O Table T18, Economic Activity Change for Shorefront Study Area

The next step in the analysis applies multipliers to each economic sector. Then, by adding up the fifty six rows in each column, the total change in economic activity in the shorefront area can be determined for each year of the eleven-year analysis period. In this case, the gross output is approximately 3 times the regional final demand change. I/O Table T18 indicates that there is an overall positive effect for the first four years, with the most substantial effect occurring in the second, third and fourth years of the construction period. The most considerable impact is reflected by the $117 million figure in the third year. Operation of the facility yields over $3 million annually. Over the eleven-year period total change comes to $271 million.

This measure of change in gross economic output for the four shorefront counties can be compared with the similar measure presented later, in I/O Table T20, for the state of New Jersey. Of course, the two estimates will vary somewhat because they are based upon two different approaches and systems of economic multipliers. Further, the state-level estimate is exepcted to be more accurate. However, comparison indicates that the two are close. The regional measure is 74 percent of the state measure, reflecting the greater provision of facility equipment and materials as opposed to tourist industry goods and services from areas of New Jersey outside of the shorefront counties.

State Area Analysis: New Jersey Social and Economic Impacts

I/O Table T19, Tourism Industry Final Demand Loss

At the state level, the loss of tourism from the shorefront region (I/O Table T10) is converted from person-days to dollars, and is presented in I/O Table T19. Each of the eleven rows corresponds to an expenditure category listed at the end of this appendix.

The numbers in the table represent the dollar loss, in thousands, of expenditures by all twenty visitor-group types in each category, for each of the eleven years. As in I/O Table T14 for the municipality, the greatest loss is sustained by category five, eating and drinking establishments. In the third year of construction the loss amounts to over $503 thousand and stays upwards of $400 thousand throughout the rest of the analysis period. Comparitively heavy losses also occur in the sixth, seventh and eighth categories--amusement and recreation, general retail trade, and groceries--with final demand losses in all three categories topping $900 thousand for the third through sixth years of the analysis period. In contrast, minimal losses are incurred in category two, automobile rental, and no losses occur in category four, campgrounds and trailer parks since these last do not exist in Lacey Township.

I/O Table T20, New Jersey Social and Economic Impacts

Overall social and economic change in New Jersey is depicted in I/O Table T20. The gross economic output, which corresponds to change in sales made by New Jersey firms, will be as high as $149 million during construction and will begin at $19 million during the first year of operation, growing slowly. This economic change is the net result of a tourism loss of $2.4 million in the third year (shown on the T20 for tourism impacts only) and gain due to facility construction expenditures of $152 million during that year (shown in the T20 for construction activities only).

Value added is considerably smaller than the gross economic output because it doesn't double count inputs. It is, thus, a truer measure of facility impact. In the third year, value added amounts to over $76 million. Throughout the operation phase it maintains a level clsoe to $11 million. This is the result of a $1.3 million third year loss due to lost tourist expenditures and an additional $1 million loss during each year of operation, offset by a $77 million peak construction year gain in the third year and a $12 gain due to facility operation.

Other measures of impact in that third year of activity include a change of employment for New Jersey of 2,720 jobs. This is the net change resulting from a loss of 74 person-years of employment in tourism related industries and a gain of 2,794 person-years of employment due to capital expenditures for construction (shown in the appropriate T20's). The average loss of employment in tourism industry-related firms

during the analysis period is 59 person-years. In the third year, New Jersey state taxes experience a net increase of $2.6 million with a tourism industry loss of $104 thousand and a facility related gain of $2.7 million. Local taxes provide a net $4.5 million in revenues, as a result of a $75 thousand loss from the tourism industry and a $4.6 million gain from construction activities.

The three tables identically titled I/O Table T20 are provided in this case study to illustrate alternative uses of the model. They are the result of applying model programs in a variety of ways to measure the net change and, separately, the positive and negative components of that change. The first I/O Table T20 presents the net change resulting from the complete case study analysis and is the major summary table. The next I/O Table T20 contains only the impact of tourist response to environmental change. It was developed by re-running P6-B and entering zero for facility activity levels. The third and final I/O Table T20 is developed by clearing I/O Table T19 and then repeating P6-B with full facility activity levels. It presents only facility purchase and employment impacts.

CASE STUDY #2
SUPPORT BASE IN LACEY TOWNSHIP

CASE STUDY #2
SUPPORT BASE IN LACEY TOWNSHIP

The Context: Lacey Township

For the second case study, an assessment is made of the social and economic impacts of a support base in Lacey Township. Lacey Township is located in Ocean County which, as discussed in Appendix E, is the largest coastal county in the study area. In the county, population doubled in the 1960's and increased by 66 percent in the 1970's, making it the fastest growing county in the state. Lacey Township, itself, experienced a population increase in the last decade of almost 300 percent. Land use is primarily residential and rural, with industrial and commercial real property comprising only 10.3 percent of the township's total assessed valuation. The Garden State Parkway passes through the townships providing excellent north-south access.

Lacey Township is classified as a northern shore year-round and rural community. The characteristics of municipalities in this classification are listed in Appendix E. Specifically, in Lacey Township, the population density is .3 persons per acre. Only 19% of the housing is for primarily seasonal use. The measure of intensity of residential development reflects both the quality and density of dwelling units and is derived from the assessed value of the homes and the ratio of the assessment to true market value. In Lacey Township this intensity is $6,675 per acre. The market value of a typical home in the township is $47,700. One of the township's major recreational attractions is the abundance of marina slips (approximately 1,000 of them) located along the western shore of Barnegat Bay.

Energy Facility: Support Base

The "proposed" energy facility in this case study is assumed to have 20 berths for supply boats for use during the exploration phase of OCS development. It will become a permanent support base to support development and production activities once initial exploration is completed. The base will require approximately 1,400 feet of wharf along

the western shore of Barnegat Bay. Some dredging will be required along the bayfront to accomodate supply boats. The total capital cost is expected to be $30,000,000 over a construction period of one year.

As shown in the facility environmental impact assessment matrix, activities during site preparation, construction and operation of the facility can effect numerous changes in the environment, both ecologically and qualitatively. For example; dredging during the construction and operation phases can cause a variety of changes including an increase in groundwater discharge and salinity, a decrease in the shoreline protection capacity, and an increase in erosion. Consequent effects of these changes on recreational resources may detract from the appeal of Lacey Township to tourists.

The environmental changes are summarized and evaluated in the Schedule of Environmental Changes (I/O Table T8) located at the end of this appendix. Perceivable thresholds for the change categories are provided in section 2.4 of the User's Guide. As shown in the schedule, the likelihood of a category one change (loss of access to a recreational resource) is high due to the pre-emption of land for approximately 1,400 linear feet of wharf footage. Dredging during the construction year is expected to cause changes in water depth and in the shoreline, resulting in a loss in quality or degree of recreational opportunity. Periodic maintenance dredging, assmed to be required every five years, is not expected to result in a quality loss. Similarly, a lowering of visual quality is expected to occur only in the construction year. The onsite storage of drilling muds, lubricants, solvents and other materials which are required to support offshore drilling operations is likely to be perceived as an introduction of a hazard to health, safety, or the environment throughout the operation phase.

Impact Path 1: Purchase of Construction Materials and Equipment

I/O Table T3, Schedule of Project Requirements

In the case of the suppport base, the construction period is one year, and the total amount appears under the first year. The construction labor force consists of 34 manual workers and 13 non-manual workers. For operations, 93 manual and 7 non-manual workers are required annually.

Impact Path 2: Construction and Operation Employment

I/O Table T4, Directly Employed Migrants

As shown in the table, no migrants are expected in any of the forty four municipalities comprising the 30-minute commuting zone. This is due to the short duration of the construction period, and the relatively small labor force requirements which can be met locally. Approximately five person-years of labor will be supplied by persons commuting long distance and migrants to the construction area, but this migration results in a probability of less than half a person-year in any municipality.

I/O Table T5, Directly Employed Previous Residents

Within the commuting zone, the 211,465 previous resident population of working age people is expected to contribute 90 percent of the manual and non-manual laborers during construction. This is the maximum proportion allowed by the model. Brick and Dover are expected to contribute the most with 6 and 7 employees, respectively. Lakewood is third with 4 workers supplied. While the support base is unusual in that its operations labor force is greater than its construction force, the assumption that operations workers are locally supplied is also reasonable in this instance. Again, Brick and Dover will supply the greatest number of workers, with 14 and 17, respectively. Lakewood is third with 9.

I/O Tables T6-A and T6-B, Unsupplied Family and Single Person Housing Demand

Unmet housing demand is unlikely to occur in the shorefront study area in the foreseeable future. This is especially true for the short construction period of a support base during which less than half a person-year of migrants are expected within any single municipality. The I/O Tables T6-A and T6-B contain all zeros in this case study.

I/O Table T7, Facility Employee Income

Facility employee income in each municipality corresponds directly to the number of workers supplied. Therefore, Brick, Dover, and Lakewood are the recipients of the greatest amounts of income. In the construction period this comes to $203, $240 and

$126 thousand, respectively. Annual operations earnings are almost double at $412, $487 and $253 thousand apiece. The case study used 1982 wage levels to represent current wages. Percentage change in the wage index (provided by BLS) was entered as zero. During future years, the percentage change between 1982 and that year wages can be entered to inflate wages presented in this table.

Impact Path 3: Tourist Response to Environmental Impacts

I/O Table T9, Tourism Diverted from Each Municipality

This table shows the number of tourists, in person-days, diverted from the environmentally affected municipality, #43, Lacey Township, to other shorefront municipalities. The eleven columns represent each year of the eleven-year analysis period, and the twenty rows correspond to the twenty visitor group types listed at the end of this appendix. The first visitor category, seasonal home/shorefront recreation is expected to incur the highest diversion rate, peaking with almost 62 thousand person-days lost in the second year (the first year of operation) and staying upwards of 40 thousand for the next seven years, before dropping back to about 38 thousand person-days per year. Exhibiting a similar pattern, except for smaller second year losses, is the category two visitor group, seasonal home/bay-water recreation. The presence of zeros in the ninth through twelfth rows indicates the absence of campsites in Lacey Township and zero values for those visitor groups in the campsite accomodation categories. Third year losses (representing a typical operation year) add up to 186, 117 visitor-days or 25.59 percent of the 727,341 annual visitor-days usually spent in the township.

I/O Table T10, Tourism Lost from Shorefront Study Area by Each Municipality

Figures in this table represent the loss of tourism, in person days, by Lacey Township from the entire shorefront region. As can be seen, the relative ranking of the twenty visitor groups is the same, but the numbers are considerably smaller, amounting to about one-fourth of the number of tourists diverted. In the seasonal home/shorefront recreation category, the number of person days lost in the second year is 18 thousand, decreasing to 14 thousand by the third year and then more gradually to over 11 thousand

by the end of the analysis period. The total number of person-days lost across the twenty visitor categories in the third year amounts to 48,463. This represents 7 percent of the total visitors in the municipality annually.

I/O Table T11, Tourism Lost from Shorefront Study Area from All Municipalities

In this case study, I/O Table T11 is identical to I/O Table T10 because only one municipality is affected and, therefore, only one T10 is produced. If the environmental effects had covered a broader area, additional tables would have been generated for each affected municipality, and I/O Table T11 would have added up the tallies for all twenty visitor types across the eleven-year period.

Municipal Area Analysis: Municipal Social and Economic Impacts

I/O Table T12, Fiscal Impact from Migration

This table presents the net result of the increased revenue provided to municipalities by migrants to the area and the costs to the municipalities of providing services to those additional people. Since there are no migrants expected in this case study, I/O Table T12 yields all zeros.

I/O Table T13, Value Lost by Seasonal Home Owners

This table estimates the opportunity cost to seasonal homeowners in Lacey Township who forego personal use or rental use of their homes. In this instance, the greatest losses are experienced in the second year of the analysis period (the first year of facility operation) at $1.6 million. In subsequent years the loss levels off to approximately $1.2 million. In a township of 1,241 seasonal homes, second year losses average $1,289 per household.

I/O Table T14, Tourism Industry Final Deman Loss

I/O Table T14 shows the loss in final demand incurred by the industries and establishments in Lacey Township dependent on the tourist trade, over each year of the eleven-year period. The eleven rows in the table correspond to a different category of

expenditure as listed at the end of this appendix. The greatest losses can be seen to occur in the fifth category, eating and drinking establishments, peaking at $1.9 million in the second year. Zeros appear in the fourth category, campgrounds and trailer parks, and the last category, gambling, because these categories are not applicable to Lacey Township. Total losses in the construction year add up to $5.6 million which is 24 percent of the $23 million annual expenditure by tourists in the municipality.

Regional Area Analysis: Shorefront Social and Economic Impacts

I/O Table T15, Regional Expenditures for Material and Equipment

The first column in the table are the WRC economic sector numbers listed at the end of this appendix. The remaining eleven columns of the twenty-six rows express, in thousand dollars, the expenditure on required material and equipment, by economic sector, during the construction phase. For the suport base, the largest expenditure is in sector #46, stone, clay and glass products, where the $2.2 million spent accounts for 56 percent of the total $3.9 million expenditure for that year and, in this case, the entire construction phase. The total $3.9 million expenditure is only 13 percent of the total capital cost of $30 million (see I/O Table T3) because it does not include wages, profits, or material and equipment purchases made outside of the shorefront region.

I/O Table T16, Tourism Industry Final Demand Loss

Tourism person-days lost by each municipality from the shorefront (I/O Table T10) are converted to tourism industry final demand loss in dollars and presented in I/O Table T16. In this case, only the five sectors whose numbers appear in the lefthand column experience losses which are traced across eleven years. Sector #56, services, incurs losses of $361 thousand in the second year with an eleven year total of $3 million (arrived at by adding across the row). Sector #54, wholesale and retail trade suffers substantial losses, as well, peaking in the second year with $278 thousand, with a total of $2.3 million across the eleven year period.

I/O Table T17, Final Demand Change for Shorefront Study Area

Facility employee income is also distributed across the WRC sectors though a separate table is not printed out since I/O Table T7 presents the same information in a more detailed form. The positive regional economic changes of Impact Paths 1 and 2 offset by the negative regional change of Impact Path 3 are presented in I/O Table T17. This time, the economic sector numbers are omitted and there are eleven columns of numbers representing each year of the analysis period. There are fifty six rows corresponding to all fifty six WRC economic sectors. Zeros appear where there is no impact or net effect. In the table, four sectors, #'s 15, 18, 34, 54, are shown to exhibit negative effects. They are oil and gas extraction, general building, other food products, and wholesale and retail trade, respectively. Twenty-five other sectors show a net gain in final demand. Sector #46, stone, clay and glass products, shows the greatest increase in any single year with $2.2 million in year one.

I/O Table T18, Economic Activity Change for Shorefront Study Area

In the regional area analysis, after the multipliers are applied in each economic sector and the fifty six rows in each column are added up to show the total economic change in the shorefront region for each year of the analysis period. I/O Table T18 indicates that there is an overall positive effect each year, peaking during the construction year at $13 million and climbing up from $3 to $4 million during the operations phase. The regional economic activity change accounts for 83 percent of the state economic activity change during the construction year, and 25 percent of the state change during operations (see gross economic output in I/O Table T20).

State Area Analysis: New Jersey Social and Economic Impacts

I/O Table T19, Tourism Industry Final Demand Loss

At the state level, the loss of tourism from the shorefront region (I/O Table T10) is converted from person-days to dollars, and is presented in I/O Table T19. Each of the eleven rows corresponds to a expenditure category listed at the end of this appendix. The numbers represent the dollar loss, in thousands, of expenditures by all twenty visitor-group types in each category, for each of the eleven years. As in I/O Table T14

for the municipality, the greatest loss is sustained by category five, eating and drinking establishments. In the second year this loss amounts to $488 thousand and stays upwards of $350 thousand for the next four years, tapering off to $300 thousand by the end of the analysis period. Comparatively heavy losses also occur in the sixth, seventh and eighth categories--amusement and recreation, general retail trade, and groceries, respectively. Zero losses occur in category four, campgrounds and trailer parks, since these do not exist in Lacey Township. Losses in category two, automobile rental are, also, quite minimal.

I/O Table T20, New Jersey Social and Economic Impacts

Overall social and economic change in New Jersey is depicted in I/O Table T20. The change in gross economic output peaks at $15.6 million in the first year (the construction year), dropping to $13.5 million at the beginning of operations and slowly climbing to $14.3 million by the end of the analysis period. These overall impacts are the result of the roughly $1.5 to $2 million in tourism loss for each year of the analysis period (shown on the T20 for the tourism loss only), and the $17.4 million impetus from construction and $15.8 million impetus from annual operations (shown on the T20 for construction and operation activities only).

In the construction year value added peaks at $6.8 million. In the first operation year, it drops back to $6.25 million but then climbs steadily to $6.7 million by the end of the analysis period. Considering tourism loss alone, value added amounts to just under $1 million during the construction of the support base, increases to $1.3 million in the first year of operation, and then declines gradually to $821 thousand by the end of the eleven-year period. Isolating construction and employment effects, it can be seen that value added comes to $7.8 million during the construction year, and maintains a level of $7.6 million throughout the operations phase.

The net change in employment averages 191.5 person-years over the eleven-year period with a peak increase of 211 person-years in the construction phase. Considering facility construction and operation alone, 266 person-years of employment are expected to be generated in the first year, with 243 person-years generated during each operation year. This is offset by the average loss of 53.5 person-years of employment due to tourism loss. Peak losses occur in the second year (first year of operation) with 72

person-years of employment eliminated. State taxes are expected to show a net average gain of $173.5 thousand per year, while local taxes show a $359 thousand yearly average increase in revenues.

CASE STUDY #3

SUPPORT BASE IN MANASQUAN TOWNSHIP

CASE STUDY #3
SUPPORT BASE IN MANASQUAN TOWNSHIP

The Context: Manasquan Township

In this third case study, the social and economic impacts of a support base in Manasquan Township are examined. Manasquan Township is located in Monmouth County, the most highly urbanized county in the study area. The coastal municipalities, like Manasquan, comprise only one quarter of the land in the county, but their population density is twice as high as the county average. The completion of the Garden State Parkway contributed to the rapid rate of growth experienced by the county in the 1950's and 1960's, transforming the area from a rural resort to a year-round commuter suburb. During the 1970's, the growth rate decreased considerably, especially in the fully developed coastal municipalities.

As a northern densely settled commuter suburb, Manasquan Township experiences the locational advantage of employment opportunity in New York City. The city is accessible by automobile or mass transit. The township itself is characterized by a population density of 6 persons per acre. Almost 29 percent of the housing is for primarily seasonal use. The measure of intensity of residential development, which reflects both the quality and density of dwelling units, is $161,753, with the value of a typical home in the township estimated to be $61,400. The township's development efforts have been primarily commercial/residential, resulting in a healthy central business district. Its major resort and recreational activities are family oriented.

Energy Facility: Support Base

The "proposed" energy facility in this case study is assumed to have 20 berths for supply boats during the exploration phase. It will be a permanent support base, designed to support development and production activities once initial exploration is completed. The base will require approximately 1,400 feet of wharf along the shore of Manasquan Bay. Some dredging will be required along the bayfront to accomodate supply boats. The total capital cost is expected to be $30,000,000 over a construction period of one year.

As shown in the facility environmental impact assessment matrix, on p. 5-54, activities during site preparation, construction and operation of the facility can effect numerous changes in the environment, both ecologically and qualitatively. For example, dredging during the construction and operation phases can cause a variety of changes including an increase in groundwater discharge and salinity, a decrease in the shoreline protection capacity, and an increase in erosion. Consequent effects of these changes on recreational resources may detract from the appeal of Manasquan Township to tourists.

The environmental changes are summarized and evaluated in the Schedule of Environmental Changes (I/O Table T8) located at the end of this appendix. Perceivable thresholds for the change categories are provided in section 2.4 of the User's Guide. As shown in the schedule, the liklihood of a category one change (loss of access to a recreational resource) is high due to the pre-emption of land for approximately 1400 linear feet of wharf frontage. Dredging during the construction year is expected to cause changes in water depth and in the shoreline, resulting in a loss in quality or degree of recreational opportunity. Periodic maintenance dredging, assumed to be required every five years, is not expected to result in a quality loss. Similarly, a lowering of visual quality is expected to result only in the construction year. The onsite storage of drilling muds, lubricants, solvents and other materials which are required to support offshore drilling operations is likely to be perceived as an introduction of a hazard to health safety, or the environment throughout the operation phase.

Impact Path 1: Purchase of Construction Materials and Equipment

I/O Table T3, Schedule of Project Requirements

In the case of the support base, the construction period is one year, and the total amount appears under the first year. The construction labor force consists of 34 manual workers and 12 non-manual workers. For operations, 93 manual and 7 non-manual workers are required annually.

Impact Path 2: Construction and Operation Employment

I/O Table T4, Directly Employed Migrants

As shown in the table, no migrants are expected in any of the sixty one municipalities comprising the 30-minute commuting zone. This is most likely due to the short duration of the construction period, and the relatively small labor force requirements which can be met locally.

I/O Table T5, Directly Employed Previous Residents

Within the commuting zone, the 409,298 previous resident population of working age persons is expected to contribute 100 percent of the manual and non-manual construction labor force. Middletown and Dover Townships will supply four workers apiece, and Brick Township will supply three. While the support base is unusual in that its operations labor force is greater than its construction labor force, the assumption that operations workers are locally supplied is also reasonable in this instance. Again, Middletown and Dover supply the greatest number of workers, nine each, and Brick is third with seven.

I/O Tables T6-A and T6-B, Unsupplied Family and Single Person Housing Demand

Unmet housing demand is a situation which is unlikely to occur in the shorefront study area in the foreseeable future. This is especially true for the short construction period of a support base in which no migrants are expected. In this case, I/O Tables T6-A and T6-B contain all zeros.

I/O Table T7, Facility Employee Income

Facility employee income in each municipality corresponds directly to the number of workers supplied. Therefore, Middletown, Dover and Brick are the recipients of the greatest amount of income. In the construction period, this comes to $129, $125, and $105 thousand, respectively. Annual operations earnings are approximately double at $263, $252, and $213 thousand apiece.

Impact Path 3: Tourist Response to Environmental Impact

I/O Table T9, Tourism Diverted from Each Municipality

This table shows the number of tourists, in person-days, diverted from the environmentally affected municipality, Manasquan, to other shorefront municipalities. The eleven columns represent each year of the eleven-year analysis period, and the twenty rows correspond to the twenty visitor types listed at the end of this appendix. The first visitor category, seasonal home/shorefront recreation, is expected to incur the highest diversion rate, peaking with 64 thousand person-days lost in the second year (the first year of operation) and staying upwards of 50 thousand for the next four years, before dropping slightly to well over 40 thousand person-days for the rest of the analysis period. Exhibiting substantial losses, as well, is the category two visitor type, seasonal home/bay water recreation. The presence of zeros in the ninth through twelfth rows indicates the absence of campsites in Manasquan Township and zero values for those visitor groups in the campsite accomodation categories. Third year losses (representing a typical operation year) add up to 160,522 person-days or 31.41 percent of the 511,004 annual person-days usually spent in the township.

I/O Table T10, Tourism Lost from Shorefront Study Area by Each Municipality

Figures in this table represent the loss of tourism, in person-days, by Manasquan Township from the entire shorefront region. As can be seen, the relative ranking of the twenty visitor groups is the same, but the numbers are considerably smaller, amounting to less than one-fourth of the number of tourists diverted. In the seasonal home/shorefront recreation category, the number of person-days lost in the second year is almost 19 thousand, decreasing to 16.7 thousand by the third year and then gradually to 12.5 thousand by the end of the analysis period. The total number of person-days lost across the twenty visitor categories in the third year amounts to 43,802. This represents 8.6 percent of the total visitors in the municipality annually.

I/O Table T11, Total Tourism Loss from Shorefront Study Area from All Municipalities

In this case study, I/O Table T11 is identical to I/O Table T10 because only one municipality is affected and, therefore, only one T10 is produced. If the environmental

effects had covered a broader area, additional tables would have been generated for each affected municipality, and I/O Table T11 would have added up the tallies for all twenty visitor types across the eleven year period.

Municipal Area Analysis: Municipal Social and Economic Impacts

I/O Table T12, Fiscal Impact from Migration

This table presents the net result of the increased revenue provided to municipalities by migrants to the area and the costs to the municipality of providing services to those additional people. Since there are no migrants expected in this case study, I/O Table T12 yields all zeros.

I/O Table T13, Value Lost by Seasonal Home Owners

This table estimates the opportunity cost to seasonal home owners in Manasquan Township who forego personal use or rental use of their homes. In this instance, the greatest losses are experienced in the second year of the analysis period (the first year of facility operation) at $1.3 million. In subsequent years the loss levels off to approximately $1 million. In a township with 897 seasonal homes, second year losses average $1,449 per household.

I/O Table T14, Tourism Final Demand Loss for Each Municipality

I/O Table T14 shows the loss in final demand incurred by the industries and establishments in Manasquan Township dependent on the tourist trade, over each year of the eleven year period. The eleven rows in the table correspond to a different category of expenditure as listed at the end of this appendix. The greatest losses can be seen to occur in the fifth category, eating and drinking establishments, peaking at $1.6 million in the second year. Zeros appear in the fourth category, campgrounds and trailer parks, and the last category, gambling, because these categories are not applicable to Manasquan Township. Total losses in the construction year add up to almost $5 million, which is 30 percent of the $16.7 million annual expenditure by tourists in the municipality.

I/O Table T15, Regional Expenditure for Materials and Equipment

The first column in the table are the WRC sector numbers listed at the end of this appendix. The remaining twenty-six rows and eleven columns of numbers express, in thousand dollars, the expenditure on required material and equipment, by sector, during the construction phase. For the support base, the largest expenditure is in sector #46, stone, clay, and glass products, where the $2.2 million spent accounts for 56 percent of the total $3.9 million expenditure for that year and, in this case, the entire construction phase. The total $3.9 million expenditure is only 13 percent of the total capital cost of $30 million (see I/O Table T3) because it does not include wages, profits, or material and equipment purchases made outside of the shorefront region.

I/O Table T16, Tourism Industry Final Demand Loss

Tourism person-days lost by each municipality from the shorefront (I/O Table T10) are converted to tourism industry final demand loss in dollars and are presented in I/O Table T16. In this case, only the five sectors whose numbers appear in the lefthand column experience losses which are traced across eleven years. Sector #56, services, incurs losses of $332 thousand in the second year with an eleven year total of $2.9 million (arrived at by adding across the row). Sector #54, wholesale and retail trade suffers substantial losses, as well, peaking in the second year with $245 thousand, with a total of $2.1 million across the eleven year period.

I/O Table T17, Final Demand Change for Shorefront Study Area

Facility employee income is also distributed across the WRC sectors though a separate table is not printed out since I/O Table T7 presents the same information in a more detailed form. The positive economic changes of Impact Paths 1 and 2, offset by the negative change of Impact Path 3 are presented in I/O Table T17. This time, the economic sector numbers are omitted and there are eleven columns of numbers representing each year of the analysis period. There are 56 rows corresponding to all 56 WRC sectors. Zeros appear where there is no impact or net effect. In the table, four sectors, numbers 15, 18, 34, and 54 are shown to exhibit negative effects. They are oil

and gas extraction, general building, other food products, and wholesale and retail trade, respectively. Twenty five other sectors show a net gain in final demand. Sector #46, stone, clay and glass products, shows the greatest increase in any single year at $2.2 million.

I/O Table T18, Economic Activity Change for Shorefront Study Area

In the regional analysis, multipliers are applied to each economic sector and the 56 rows in each column are added up to show the total economic change in the shorefront region for each year of the analysis period. I/O Table T18 indicates that there is an overall positive effect each year, peaking during the construction year at $13 million and increasing gradually from $3.3 million during the first year of operation to $4.3 million by the end of the analysis period. The regional economic activity change accounts for 84 percent of the state activity change during the construction year, and 26 percent of the state change during operations (see gross economic output in I/O Table T20).

State Area Analysis: New Jersey Social and Economic Impacts

I/O Table T19, Tourism Industry Final Demand Loss

At the state level, the loss of tourism from the shorefront region (I/O Table T10) is converted from person-days to dollars, and is presented in I/O Table T19. Each of the eleven rows corresponds to the expenditure category listed at the end of this appendix. The numbers represent the dollar loss, in thousands, of expenditures by all twenty visitor-group types in each category, for each of the eleven years. As in I/O Table T14 for the municipality, the greatest loss is sustained by category five, eating and drinking establishments. In the second year this loss amounts to $436 thousand and stays upwards of $300 thousand for the next four years, tapering off to $257 thousand by the end of the analysis period. Comparatively heavy losses also occur in the sixth, seventh and eighth categories: amusement and recreation, general retail trade, and groceries, respectively. Zero losses occur in category four, campgrounds and trailer parks, since these do not exist in Manasquan Township. Losses in category two, automobile rental are, also, quite minimal.

I/O Table T20, New Jersey Social and Economic Impacts

Overall social and economic change in New Jersey is depicted in I/O Table T20. The change in gross economic output peaks at $15.7 million in the first year (the construction year), dropping to $13.7 million at the beginning of operations and slowly climbing to $14.6 million by the end of the analysis period. These overall impacts are the result of the roughly $1.3 to $1.7 million lost each year of the analysis period, as shown on the T20 for tourism loss only, and the $17.4 million impetus from construction and $15.8 million impetus from annual operations shown on the T20 for construction and operating activities only.

In the construction year value added peaks at $6.9 million. In the first operation year, it drops back to $6.4 million but then creeps steadily upward to $6.8 million by the end of the analysis period. Considering tourism loss alone, value added amounts to just under $950 thousand during the construction of the support base, increases to $1.2 million in the first year of operation, and then declines gradually to $708 thousand by the end of the eleven-year period. Isolating construction and employment effects, it can be seen that value added comes to $7.8 million during the construction year, and maintains a level of $7.6 million throughout the operations phase.

The net change in employment averages $197 person-years over the eleven year period with a peak increase of 214 person-years in the construction phase. Considering facility construction and operation alone, 266 person-years of employment are expected to be generated in the first year, with 243 person-years generated during each operation year. This is offset by the average loss of 48 person-years of employment due to tourism loss. Peak losses occur in the second year (first year of operation) with 64 person-years of employment eliminated. State taxes are expected to show a net average gain of $181 thousand per year, while local taxes show a $364 thousand average increase in revenues.

CASE STUDY #4
COAL-FIRED POWER PLANT IN MIDDLE TOWNSHIP

CASE STUDY #4
COAL-FIRED PLANT IN MIDDLE TOWNSHIP

The Context: Middle Township

The fourth case study considers the social and economic impacts of a coal-fired power plant in Middle Township. Middle Township is located in Cape May County which, as discussed in Appendix E, is the smallest of the four counties in the study area in terms of both population size and land area. Most of the mainland communities in the county are classified as rural,year round. Ten percent of the land is on island communities that house 50 percent of the county's permanent population and account for two-thirds to three-fourths of all developed land. Resort land use accounts for at least 60 percent of all developed land. The Cape May economy is highly seasonal, based almost totally on the recreation tourism industry. Ninety percent of the land value in the county is directly or indirectly invested in the resort economy. By the end of the 1980's, the population of permanent residents is expected to increase by one-third, and the summer population should grow by 11 percent, both substantially slower growth rates than those experienced in the previous decade.

Middle Township is classified as a southern shore year-round rural community. The characteristics of municipalities in this classification are listed in Appendix E. Specifically, Middle Township is characterized by a population density of .2 persons per acre. Only 21.5 percent of the housing is considered to be primarily seasonal. The measure of intensity of residential development, which reflects both the quality and density of dwelling units, is $3,843, with the market value of a typical home in the township estimated to be $39,500. Middle Township is a relatively older community in which development efforts have focused on the preservation of historical structures.

Energy Facility: Coal-fired Power Plant

The "proposed" energy facility in this case study is a 500 megawatt unit with a total capital cost of $468,800,000 to be constructed over a five year period. The facility would utilize a closed cooling system, minimizing the need for water from adjacent Grassy Bay. Coal is anticipated to arrive at the plant site by rail, though the site fronts

along Grassy Bay, permitting installation of large unloading equipment should it become desirable.

As shown in the facility environmental impact assessment matrix on p. 5-56, activities during site preparation, construction and operation of the plant can affect numerous changes in the environment both ecologically and qualitatively. For example, faunal abundance may be decreased by the removal of surficial soils and vegetation during the site preparation phase. This activity may also generate a significant amount of dust that may detract from the appeal of Middle Township to tourists.

The environmental changes are summarized and evaluated in the Schedule of Environmental Changes (I/O Table T8) located at the end of this appendix. Perceivable thresholds for the change categories are provided in section 2.4 of the User's Guide. As shown in the schedule, the likelihood of a category one change (loss of access to a recreational resource) is high due to the preemption of a significant amount of waterfront acreage. A loss in the quality or degree of recreational opportunity is expected to occur during the third, fourth, and fifth years of the construction period as a result of the decrease in faunal abundance and traffic congestion caused by construction activity during these years. Note that water depth and shoreline changes in this category are considered to be low or minimal. This is because, in most locations in the study area, a coal-fired power plant would receive coal by rail, minimizing the dredging and channeling activities that could cause these changes. From the third year of construction on, there is a high probability of the lowering of visual and other aesthetic qualities. While the major structures of a coal-fired power plant are quite high and visible over a large area, the plant's inland location would limit its visibility to less than one mile of ocean front. The corresponding probability of visual marring of the ocean front is listed in the schedule as low. Finally, it is assumed that tourists do not perceive the operation of a state-of-the-art coal-fired power plant as producing toxic substances, pathogens or hazardous substances. Consequently, the probabilities of the introduction of hazards and temporary loss of resources due to pollution are low or minimal.

Impact Path 1: Purchase of Construction Materials and Equipment

I/O Table T3, Schedule of Project Requirements

The first I/O Table, T3 shows the total capital cost of $468,800,000, divided out by the fraction of completed construction for each year of the construction period. The number of manual and non-manual construction employees is listed for each year of the construction period, as given in Appendix B. For the remainder of the eleven-year analysis period, the annual operations labor force in both the manual and non-manual categories appears as 90 and 12, respectively.

I/O Table T4, Directly Employed Migrants

I/O Table T4 shows, by municipality and year, the number of directly employed migrants drawn to the region by employment opportunities at the plant. The information is presented in eleven columns, one for each year of the analysis period, and twenty nine rows, each corresponding to the municipality number and name listed in the last two columns on the right. These twenty nine municipalities comprise the 30-minute commuting zone around Middle Township. As can be seen, municipalities 0102 (Atlantic City) and 0505 (Lower) are the only municipalities expected to receive migrant employees, 168 and 67 in person-years, respectively, over the five-year construction period. In the peak year of construction, year three, 108 migrants will be brought to the region. Ones appear from the sixth column on for Atlantic City to show that one person will migrate to the area during each year of operation.

I/O Table T5, Directly Employed Previous Residents

Within the zone, the 117,318 previous resident population of working age people is expected to contribute 73 percent of the manual laborers and 46 percent of the non-manual laborers during construction. A breakdown of these workers by municipality and year appears in I/O Table T5. During the construction period--the first five years represented by the first five columns--the numbers assume a fairly normal distribution, increasing substantially in the second year, peaking in the third and tapering off quite dramatically between the fourth and fifth year. In the sixth through eleventh years, the relatively smaller operations labor force is shown as constants. The employment effect

in any municipality can be found by tracing the row with the appropriate municipality number and name listed at the right across the eleven-year period. Again, Atlantic City and Lower lead the twenty nine municipalities with the largest numbers of previous residents employed. In the third column, and peak year of construction, 173 Atlantic City residents and 76 Lower residents will be employed at the plant. By adding up the first five columns, it can be seen that construction period person-years of employment total 376 in Atlantic City and 165 in Lower. For each year of plant operation, there are 18 and 8 person-years of labor supplied, respectively.

I/O Tables T6-A and T6-B, Unsupplied Family and Single Person Housing Demand

I/O Tables T6-A and T6-B present the Unsupplied Family and Unsupplied Single-Person housing demand in each municipality within the commuting zone. In this case, family housing demand in the more populous municipalities (population of 15,000 or more) of the commuting zone is 70 units. Since this is 0.6 percent of the total number of owner occupied housing of 10,785 in the same municipalities, an excess family housing demand of 11.8 units in Atlantic City and 4.7 units in Lower may result in the third year. In all other years and for single person homes in all years, incoming migrants amount to less than one-half of one percent of the housing supply, the amount needed to define an excess housing demand. The existence of this demand in the third year is unusual for a region that has an abundant supply of second and seasonal homes. It is most likely attributable to the relatively low number of owner occupied homes in the township coupled with increased numbers of migrants during the peak construction year.

I/O Table T7, Facility Employee Income

I/O Table T7 presents the earnings of resident and migrant employees for each year of the eleven-year analysis period. For the five-year construction period, the pattern of incremental increases and decreases from year to year corresponds directly to the change in the number of employees shown in I/O Tables T4 and T5. Consequently, the municipalities which are the recipients of the greatest amount of employee income are Atlantic City and Lower. In Atlantic City, facility employee income peaks at $8.2 million in the third year and amounts to $17.8 million if the five-year construction period income is added together. In the operation phase, $539 thousand of income is earned annually by Atlantic City residents. Note that the figures in the table reflect the

income of both migrants ad previous residents in each municipality. The closest approximation of the portion attributable to one group or the other is the number of employees in one group as compared to the total number of employees supplied by the municipality (i.e., add together the figures from I/O Tables T4 and T5). This fraction is then applied to the dollar value listed in I/O Table T7.

Impact Path 3. Tourist Response to Environmental Impacts

I/O Table T9, Tourism Diverted from Each Municipality

I/O Table T9 shows the number of tourists, in person days, diverted from the environmentally affected municipality which, in this case, is indicated in the title as #78, Middle Township. There are eleven columns of numbers, representing each year of the analysis period, and twenty rows corresponding to the twenty visitor types. These twenty types are keyed to the list found at the end of this appendix. The ninth row refers to the ninth visitor type, campground/shorefront recreation, which in this case will be diverted to other shorefront municipalities at the rate of 33,576 person-days in the first year, peaking at 201,025 person-days in the fifth and losing between 156,000 and 186,000 person-days of tourism each successive year of operation. Category ten, campground/bay-water recreation, also incurs substantial losses which amount to 191,068 in the fifth year and stay upwards of 172,000 for the remainder of the analysis period. Total losses in the third year, the peak year of construction, add up to 871,297 person-days which is 43.67 percent of the 1,995,196 person-days annually spent in the municipality by tourists.

I/O Table T10, Tourism Lost from Shorefront Study Area by Each Municipality

I/O Table T10 is similar to T9 except that the figures represent the tourism lost by Lacey Township from the entire shorefront region. As can be seen, the relative ranking of the twenty visitor groups is the same, but these losses are considerably smaller. During the construction phase less than one-fourth as many person-days diverted in the campground/shorefront recreation category are lost from the shorefront region entirely. For example, in the fifth year, 45,231 person-days are lost in that category as compared to 201,025 diverted. Tourism loss from the shorefront is less than tourism diverted from the municipality because many visitors who respond to environmental change will move

their recreational activities to a nearby municipality. The total tourism loss in the third year amounts to 198,338 person-days or 10 percent of the total annual person-days.

I/O Table T11, Tourism Lost from Shorefront Study Area from All Municipalities

In this case study, I/O Table T11 is identical to I/O Table T10 because only one municipality is affected and, therefore, only one T10 is produced. If the environmental effects had covered a broader area, additional tables would have been generated for each affected municipality, and I/O Table T11 would have added up the tallies for all twenty visitor types across the eleven-year period.

I/O Table T12, Fiscal Impact From Migration

I/O Table T12 presents the net result of the increased revenue provided to municipalities by migrants to the area and the costs to the municipalities of providing services to those additional people. Non-zero figures appear only in those rows corresponding to those municipalities listed in I/O Table T4 as being recipients of migrants. As exhibited in the table, the cost of providing municipal services outweighs increased revenues. In Lower the cost peaks in the third year at $4 thousand and then becomes quite insignificant by the end of the construction period. However, in Atlantic City, during the construction period, the negative fiscal impact is high in the second, third and fourth year. The third year costs alone amount to $57 thousand.

I/O Table T13, Value Lost by Seasonal Home Owners

I/O Table T13 estimates the opportunity cost to seasonal home owners in Middle Township who forego personal use or rental use of their homes. In this instance, the greatest losses are experienced in the third year at $1.3 million. Subsequent years show losses of approximately $1.2 million each. In a township of 1,218 seasonal homes, third year losses average $1,067 per household.

I/O Table T14, Tourism Industry Final Demand Loss

I/O Table T14 shows the loss in final demand incurred by the industries and establishments in Middle Township dependent on tourist trade, over each year of the

eleven-year analysis period. The eleven rows in the table each correspond to a different category of expenditure as listed at the end of this appendix. In the table, the greatest losses can be seen to occur in the fifth category, eating and drinking establishments, where from the third year on losses amount to over $10 million. Zeros appear in the last category, gambling, because this category is not applicable to Middle Township. Total third year losses amount to $32.3 million or 45 percent of the $72.4 million annual expenditures made in the township by tourists.

Regional Area Analysis: Shorefront Social and Economic Impacts

I/O Table T15, Regional Expenditures for Material and Equipment

I/O Table T15 has twenty five rows which along the last eleven columns express, in thousand dollars, the expenditure within the shorefront counties on required material and equipment, by economic sector, for each year of the construction phase. The first column of numbers identify the economic sector receiving expenditures shown in an individual row. The numbers are keyed to the list of Water Resource Council Sectors at the end of this appendix. For example, the largest amount of expenditures within the region for a coal-fired power plant are made in sector #47, primary metal industries with $7.3 million worth made in the third year of construction, alone. This represents 50 percent of the total $14.6 million spent in year three. The year three total expenditure is only 6.8 percent of the capital expenditure for that year for facility construction (see I/O Table T3). It is proportionately small because it does not include wages, profits, or material and equipment purchases made outside of the shorefront region.

I/O Table T16, Tourism Industy Final Demand Loss

Tourism person-days lost by each municipality from the shorefront (I/O Table T10) are converted to tourism industry final demand loss in dollars and presented in I/O Table T16. This loss is distributed across all of the affected WRC economic sectors. In this case only five sectors are affected. Sector numbers appear in the first column with losses traced across eleven years in the following columns. Sector #56, Services, experiences the greatest loss ($17.4 million over the analysis period) with sector #54, wholesale and retail trade second, ($8.8 million over the same period). Total tourism industry final demand loss in the region was almost $3.6 million in year three or 47

percent of all tourist trade lost (see third column I/O Table T19) because most tourist expenditures are made for imported goods.

I/O Table T17, Final Demand Change for Shorefront Study Area

Facility employee income is also distributed across the WRC sectors, though a separate table is not printed out since I/O Table T7 presents the same information in a more detailed form. The positive regional economic changes of Impact Paths 1 and 2 offset by the negative regional economic change of Impact Path 3 are presented in I/O Table T17. This time, the economic sector numbers are omitted and there are eleven columns of numbers representing each year of the analysis period. There are fifty six rows corresponding to all fifty six WRC economic sectors. Zeros appear where there is no impact at all or no net effect. In the table, five sectors are shown to experience a net negative effect at some point during the eleven-year period. They are sector numbers 15, 18, 34, 54, and 56. Sector #56, services, experiences losses in the operations phase that range from $1.2 million to $1.6 million. Twenty one sectors experience positive effects which, as in the case of sector numbers 47 and 55, can be quite substantial. Note that some sectors are only affected through the construction phase, while others experience increases or decreases for the duration of annual operation.

I/O Table T18, Economic Activity Change for Shorefront Study Area

The next step in the analysis applies multipliers to each economic sector. Then, by adding up the fifty six rows in each column, the total change in economic activity in the shorefront area can be determined for each year of the eleven year analysis period. I/O Table T18 indicates that there is an overall positive effect for the first four years, with the most substantial effect occuring in the third year amounting to $105 million. However, from the fifth year on, losses of more than $4 million result with higher losses occurring in the sixth year or first year of operation.

State Area Analysis: New Jersey Social and Economic Impacts

I/O Table T19, Tourism Industry Final Demand Loss

At the state level, the loss of tourism from the shorefront region (I/O Table T10) is converted from person-days to dollars, and is presented in I/O Table T19. Each of the eleven rows corresponds to an expenditure category listed at the end of this appendix. The numbers in the table represent the dollar loss, in thousands, of expenditures by all twenty visitor-group types in each category, for each of the eleven years. As in I/O Table T14 for the municipality, the greatest loss is sustained by category five, eating and drinking establishments. In the third year of construction the loss amounts to over $2.3 million and stays close to $2 million throughout the rest of the analysis period. Comparitively heavy losses also occur in the sixth, seventh and eighth categories--amusement and recreation, general retail trade, and groceries--with final demand losses in all three categories topping $900 thousand for the last nine years of the analysis period. In contrast, minimal losses are incurred in category two, automobile rental.

I/O Table T20, New Jersey Social and Economic Impacts

Overall social and economic change in New Jersey is depicted in I/O Table T20. The gross economic output, which corresponds to change in sales made by New Jersey firms, will be as high as $142 million during construction and will begin at $12 million during the first year of operation, growing slowly. This economic change is the net result of a tourism loss of $10 million in the third year (shown on the T20 for tourism impacts only) and gain due to facility construction expenditures of $152 million during that year (shown in the T20 for construction activities only).

Other measures of impact in that third year of activity include a change of employment for New Jersey of 2,466 jobs. This is the net change resulting from a loss of 329 person-years of employment in tourism related industries and a gain of 2,794 person years of employment due to capital expenditures for construction (shown in the appropriate T20's). In the third year value added amounts to $72 million. Throughout the operations phase it climbs from $6.9 million to $7.5 million. New Jersey state taxes experience a net increase of $2.3 million with a tourism industry loss of $458 thousand and a facility related gain of $2.7 million. Local taxes provide a net $4.3 million in

revenues, as a result of an $316 thousand loss from the tourism industry and a $4.6 million gain from construction activities.

CASE STUDY #5

SUPPORT BASE IN OCEAN CITY

CASE STUDY #5
SUPPORT BASE IN OCEAN CITY

The Context: Ocean City

In this fifth case study, the social and economic impacts of a support base in Ocean City are examined. Ocean City is located in Cape May County which, as discussed in Appendix E, is the smallest of the four counties in the study area in terms of both population size and land area. Most of the mainland communities in the county are classified as rural, year round. Ten percent of the land is on island communities that house 50 percent of the county's permanent population and account for two-thirds to three-fourths of all developed land. Resort land use accounts for at least 60 percent of all developed land. The Cape May economy is highly seasonal, based almost totally on the recreation tourism industry. Ninety percent of the land value in the county is directly or indirectly invested in the resort economy. By the end of the 1980's, the population of permanent residents is expected to increase by one-third, and the summer population should grow by 11 percent, both substantially slower growth rates than those experienced in the previous decade.

Ocean City is classified as a southern, shorefront seasonal community. The characteristics of municipalities in this classification are listed in Appendix E. Specifically, Ocean City is characterized by a population density of 3.7 persons per acre. A large percentage (over 59) of the homes in the city are used seasonally. The measure of intensity of residential development, which reflects both the quality and density of dwelling units is $252,244, with the market value of a typical home in the township estimated to be $77,100. A resort and amusement center, Ocean City attracts the largest number of visitors in the county.

Energy Facility: Support Base

The "proposed" energy facility in this case study is assumed to have 20 berths for supply boats for use during the exploration phase of OCS development. It will become a permanent support base to support development and production activities once initial exploration is completed. The base will require approximately 1,400 feet of wharf along Great Egg Harbor. Some dredging will be required along the bayfront to accommodate

supply boats. The total capital cost is expected to be $30,000,000 over a construction period of one year.

As shown in the facility environmental impact assessment matrix at the end of this appendix, activities during site preparation, construction and operation of the facility can effect numerous changes in the environment, both ecologically and qualitatively. For example, dredging during the construction and operation phases can cause a variety of changes including an increase in groundwater discharge and salinity, a decrease in the shoreline protection capacity, and an increase in erosion. Consequent effects of these changes on recreational resources may detract from the appeal of Ocean City to tourists.

The environmental changes are summarized and evaluated in the Schedule of Environmental Changes (I/O Table T8) located at the end of this appendix. Perceivable thresholds for the change categories are provided in section 2-4 of the User's Guide. As shown in the schedule, the likelihood of a category one change (loss of access to a recreational resource) is high due to the pre-emption of land for approximately 1,400 linear feet of wharf footage. Dredging during the construction year is expected to cause changes in water depth and in the shoreline, resulting in a loss in quality or degree of recreational opportunity. Periodic maintenance dredging, assumed to be required every five years, is not expected to result in a quality loss. Similarly, a lowering of visual quality is expected to occur only in the construction year. The onsite storage of drilling muds, lubricants, solvents and other materials which are required to support offshore drilling operations is likely to be perceived as an introduction of a hazard to health, safety, or the environment throughout the operation phase.

Impact Path 1: Purchase of Construction Materials and Equipment

I/O Table T3, Schedule of Project Requirements

In the case of the support base, the construction period is one year, and the total amount appears under the first year. The construction labor force consists of 34 manual workers and 12 non-manual workers. For operations, 93 manual and 7 non-manual workers are required annually.

Impact Path 2: Construction and Operation Employment

I/O Table T4, Directly Employed Migrants

As shown in the table, of the thirty municipalities comprising the 30-minute zone, only Atlantic City can expect migration and then, only one person-year. This is most likely due to the short duration of the construction period, and the relatively small labor force requirements which can be met locally. Only fractions of a person-year will migrate to some of the other municipalities. These are rounded down to zeros.

I/O Table T5, Directly Employed Previous Residents

Within the commuting zone, the 125,983 previous resident population of working persons is expected to contribute virtually all of the manual and non-manual construction labor force. Atlantic City supplies the most labor with seven person-years and Galloway, Ocean City and Lower will supply three workers a piece. While the support base is unusual in that its operations labor force is greater than its construction labor force, the assumption that operations workers are locally supplied is also reasonable in this instance. Atlantic City provides the most operations workers, with 17, and Lower is second with seven.

I/O Table T6-A and T6-B, Unsupplied Family and Single Person Housing Demand

Unmet housing demand is unlikely to occur in a situation where there is such a short construction period and no influx of migrants. Hence, in this case study, these tables contain all zeros.

I/O Table T7, Facility Employee Income

Facility employee income in each municipality corresponds directly to the number of workers supplied. Therefore, Atlantic City, Lower, Galloway and Ocean City are the recipients of the greatest amount of income. In the construction period, this covers to $257, $112, $83, and $83, respectively. Annual operations earnings are approximately double at $487, $215, $174, and $175 a piece.

Impact Path 3: Tourist Response to Environmental Impacts

I/O Table T9, Tourism Diverted from Each Municipality

In this table, the first visitor category, seasonal home/shorefront recreation, is expected to incur the highest diversion rate, peaking with 586 thousand person-days lost in the second year and staying upwards of 419 thousand for the rest of the analysis period. Exhibiting substantial losses, as well, is the category two visitor type, seasonal home/bay-water recreation. The presence of zeros in the ninth through twelfth categories indicates the absence of campsites in Ocean City. Third year losses (representing a typical operation year) add up to 1,286,543 person-days or 24.68 percent of the 5,223,458 annual person-days of tourism.

I/O Table T10, Tourism Lost from Shorefront Study Area by Each Municipality

The relative ranking of the twenty visitor groups is the same as in I/O Table T9, but the numbers are considerably smaller, amounting to about one-third to one-fourth the number of tourists diverted. In the seasonal home/shorefront recreational category, the number of person-days lost in the second year (first year of operation is 173 thousand) decreasing to 140 thousand by the third year and then gradually to 124 thousand by the end of the analysis period. The total number of person-days lost across the twenty visitor categories in the third year (a typical year of operation) amounts to 3,406,19. This represents 6.5 prcent of the total visitors in the municipality annually.

I/O Table T11, Total Tourism Lost from Shorefront Study Area from All Municipalities

This summary table is identical to I/O Table T10 because only one municipality is environmentally affected and, therefore, only one T10 is produced.

Municipal Area Analysis: Municipal Social and Economic Impacts

I/O Table T12, Fiscal Impact from Migration

Since no migrants are expected in this case study, I/O Table T12 yields all zeros except for a $700 negative impact in Atlantic City during the construction year which is attributable to the sole migrant person-year expected that year.

I/O Table T13, Value Lost by Seasonal Home Owners

This table estimates the opportunity cost to seasonal home owners in Ocean City who forego personal use or rental use of their homes. In this instance, the greatest losses are experienced in the second year of the analysis period (the first year of operation) at $12.3 million. In subsequent years, the loss levels off to approximately $10 million. In a city with 9,921 seasonal homes, second year losses average $1,240 per household.

I/O Table T14, Tourism Final Demand Loss for Each Municipality

The greatest losses in final demand can be seen to occur in the fifth category, eating and drinking establishments, peaking at $13 million in the second year. Zeros appear in the fourth category, campgrounds and trailer parks, and the last category, gambling, because these are not applicable to Ocean City. Total losses in the peak construction year add up to $44.4 million, which is 26 percent of the $171 million expended annually by tourists in the city.

Regional Area Analysis: Shorefront Social and Economic Impacts

I/O Table T15, Regional Expenditure for Materials and Equipment

The first column in the table is the WRC sector numbers listed at the end of this appendix. The remaining twenty six rows and eleven columns of numbers express, in thousand dollars, the expenditure on required material and equipment, by sector, during the construction phase. For the support base, the largest expenditure is in section #46, stone, clay and glass products, where the $2.2 million spent accounts for 56 percent of

the total $3.9 million expenditure for that year and, in this case, the entire construction phase. The total $3.9 million expenditure is only 13 percent of the total capital cost of $30 million (see I/O Table T3) because it does not include wages, profits, or material and equipment purchases made outside of the shorefront region.

I/O Table T16, Tourism Industry Final Demand Loss

Tourism person-days lost by each municipality from the shorefront (I/O Table T10) are converted to tourism industry final demand loss in dollars and are presented in I/O Table T16. In this case, only the five sectors whose numbers appear in the left hand column experience losses which are traced across eleven years. Sector #56, services, incurs losses of $2.8 million in the second year with an eleven year total of $23 million.

I/O Table T17, Final Demand Change for Shorefront Study Area

The positive economic changes of Impact Paths 1 and 2, offset by the negative change of Impact Path 3 are presented in I/O Table T17. This time, the economic sector numbers are omitted and there are eleven columns of numbers representing each year of the analysis period. There are 56 rows corresponding to all 56 WRC sectors. Zeros appear where there is no impact or net effect. In the table, four sectors, numbers 15, 18, 34, and 54 are shown to exhibit negative effects. They are oil and gas extraction, general building, other food products, and wholesale and retail trade, respectively. Twenty five other sectors show a net gain in final demand. Sector #46, stone, clay and glass products, shows the greatest increase in any single year at $2.2 million.

I/O Table T18, Economic Activity Change for Shorefront Study Area

In the regional analysis, the multipliers are applied to each economic sector and the 56 rows in each column are added up to show the total economic change in the shorefront region for each year of the analysis period. I/O Table T18 indicates that there is an overall negative effect each year, peaking during the first operation year at $14.7 million and sustaining losses of over $10 million during the next two years before declining steadily to about $7.6 million by the end of the analysis period.

I/O Table T19

At the state level, the loss of tourism from the shorefront region (I/O Table T10) is converted from person-days to dollars, and is presented in I/O Table T19. Each of the eleven rows corresonds to the expenditure category listed on p. 5-64. The numbers represent the dollar loss, in thousands, of expenditures by all twenty visitor-group types in each category, for each of the eleven years. As in I/O Table T14 for the municipality, the greatest loss is incurred by category five, eating and drinking establishments. In the second year this loss amounts to $3.5 million and stays upwards of $2 million for the duration of the analysis period. Comparatively heavy losses also occur in the sixth, seventh and eighth categories: amusement and recreational, general retail trade, and groceries, respectively. Zero losses occur in category four, campgrounds and trailer parks, since these do not exist in Manasquan Township.

I/O Table T20, New Jersey Social and Economic Impacts

Overall social and economic change in New Jersey is depicted in I/O Table T20. The change in gross economic output is, at first, a $2.4 million positive change, then it drops dramatically to a negative $1.2 million, increases the following year to a positive $1.9 million and climbs to $4.7 million by the end of the analysis period. The construction and employment contribution to this pattern can be seen on the T20 for facility activities only. The gross economic output comes to $17.4 million during the construction year and $15.8 million during annual operations. This is offset by large losses in output due to tourism loss (see T20 for tourism loss only) during the first two years of $15 and $17 million, decreasing each subsequent year of the analysis period to $11 million.

During the first three years, net value added is negative, amounting to $2 million loss during the first operation year, and steadily increasing in subsequent years to a positve $1.3 million by the end of the analysis period. This is the result of a negative effect due to tourism loss of $9.6 million by the second year, declining to $6.3 by the end of the eleven-year period, offset by a positive facility related effect of $7.8 million in the first year and $7.6 each year of operation.

The net change in employment averages a loss of 156 person-years, peaking in the first operation year with a negative 285 person-years. Considering facility construction and operation alone, 266 person-years of employment are expected to be generated in the first year, with 243 person-years generated during each operation year. This is offset by the average loss of 401 person-years of employment due to tourism loss. Peak losses occur in the second year with 528 person-years of employment eliminated. State taxes are expected to show a net average of $548 thousand per year, while local taxes show a 408 thousand average yearly loss in revenues.

NOTE: The following four pages contain information from the New Jersey Shorefront Municipality Data Base. The data base contains over 50 variables, or items of information, on the social, fiscal, demographic and physical characteristics of each of the 127 municipalities within the four-county shorefront region, of which the study area is a part. When accessed by the model user, the data base provides two screen pages of information on each municipality. The screen pages of the four municipalities considered in the case studies have been reprinted here, exactly as they appear on the screen, for the convenience of the reader.

1.	Municipality	LACEY	16.	Pop. over 65	2,539
